Clinical Study of Isolated Zygomatic Fractures

N Nagaprasad¹, Praveen Harish G², Gurrala Sharath Chandra Reddy³

ABSTRACT

Introduction: Facial injuries deserve special attention because of their enormous functional and aesthetic significance. Aim of the study was to assess the causes and management of patients admitted with Zygomatic fractures evaluate the protocol for surgical management. To emphasise on the indications for closed and open reduction.

Material and Methods: This is a prospective study which was done on 52 patients over a period of 24 months. Patients with isolated zygomatic fractures, both sexes and all age groups were included.

Results: This study encompassed a total number of 52 patients with Zygoma fractures 50 (96.15%) patients were Male and 2 (3.85%) patients were Female with Male to Female ratio of 26:1. Most common age group involved in this study was 20-30 years (57.69%). Most common risk factors identified in this study was road traffic accidents which accounted for majority of the cases (83%) followed by interpersonal violence cases (10%) and accidental falls (7%). In our study out of 52 Zygomatic bone fractures. The most prevalent fractures were on right side. In our study the commonest presenting feature is subconjunctival haemorrhage (92%) followed by circum orbital ecchymosis (90%), Trismus (61%), malar flattening (60%) and numbness in the infra orbital nerve distribution (5%). In our study 32 patients (61.53%) underwent closed reduction by Gilles method and 20 patients (38.47%) underwent open reduction and internal fixation with miniplates and screws. 10 patients were treated with both Gilles elevation and ORIF. Zygomatic Arch fractures were 27 (51.92%) and Zygomatic comlex fractures were 32 (57.69%). Single point fixation was done in 17 patients at Zygomaticomaxillary buttress and 3 patients had 2 point fixation at ZygomaticoMaxillary and Zygomatico Frontal sutures. Single point fixation in the ZM area in Zygomatic complex fractures can avoid unsightly scars and give high satisfaction with surgical outcomes in selected patients with fracture displacement.

Conclusion: It was concluded that the high frequency of Zygomatic fractures due to RTA in our population highlights the need for the strict enforcement of traffic rules and regulations. In view of the avoidable morbidity and mortality due to inadequate treatment, we advocate the establishment of regionalized, efficient, and focused trauma centers in various parts of the state particularly for acute trauma.

Key words: Zygomatic fractures, Subconjunctival haemorrhage, Gilles method.

INTRODUCTION

The maxillofacial region occupies the most prominent position in the human body and rendering it vulnerable to injuries quite commonly. Maxillofacial injuries are commonly encountered in the practice of emergency medicine and are often associated with high morbidity resulting from increased costs of care and varying degrees of physical, functional and cosmetic disfigurement. The etiology of maxillofacial injuries varies from one country to another and even within the same country depending on the prevailing socioeconomic, cultural and environmental factors, so also the management. This study aims to see the patterns of Isolated Zygomatic bone fractures and their management. The common etiologies of Zygomatic fractures, across the world, are road traffic accidents, falls, assaults, firearm injury, sports and industrial accidents. Road traffic accident is reported to be the leading cause of Zygomatic fractures in developing countries while interpersonal violence is the leading cause in developed countries. The causes and pattern of Zygomatic injuries reflect trauma patterns within the community and, as such, can provide a guide to the design of programs geared toward prevention and treatment. Maxillofacial injuries involve soft and hard tissues injuries of face extending from frontal bone superiorly to mandible inferiorly and vary from soft tissue lacerations to complex fractures of Maxillofacial skeleton. The pattern of these injuries depends on the mechanism of injury, magnitude and direction of impact force and anatomical site.

This study was aimed to assess the causes and management of patients admitted with Zygomatic fractures evaluate the protocol for surgical management and to emphasise on the indications for closed and open reduction.

MATERIAL AND METHODS

This is a prospective study which was done on 52 patients with zygomatic fractures admitted in department of plastic surgery over a period of 24 months from January 2012 to December 2013, it was done in Osmania General Hospital. Informed consent from the patients and ethical clearance from the institute was taken before the start of the study.

Inclusion Criteria: Patients with isolated zygomatic fractures, both sexes and all age groups were included.

Exclusion Criteria: Patients with other associated fractures were excluded.

A detailed history with respect to sex, age, aetiology, nature and type of injury and fractures of the Zygomatic region their management and complications were analyzed. Fractures of the Mandible, Maxilla, Nasal bones and pan facial fractures and fractures of the orbit and frontal bones are excluded from this study. Diagnosis was based on detailed history and a thorough clinical examination, confirmed by radiographic investigations like digital x-rays, OPG, CT scan apart from routine investigations like digital x-rays, OPG, CT scan.

investigations like CBP, blood grouping, chest X-ray. Time of injury to treatment was noted. Those patients with associated head, chest and abdominal injuries were referred as and when required. The surgical interventions used were closed reduction (Gilles method) or open reduction and internal rigid fixation with miniplates, and screws, as appropriate. Complications studied included Infection, Malocclusion, Malunion, and need for implant removal, Diplopia, Enophthalmos, Mouth opening limitation.

STATISTICAL ANALYSIS
SPSS version 21 was used for statistical analysis. Data were presented by descriptive analysis.

RESULTS
This study encompassed a total number of 52 patients with Zygoma fractures. 50 (96.15%) patients were Male and 2 (3.85%) patients were Female with Male to Female ratio of 26:1. Most common age group involved in this study was 20-30 years (57.69%) followed by 31-40 years (26.92%), least No. of cases recorded in above 50 years age group (5.76 %) and the patients age group ranged from 20 to 65 years. Most common risk factors identified in this study was Road traffic accidents which accounted for majority of the cases (83%) followed by interpersonal violence cases (10%) and accidental falls (7%). In our study out of 52 Zygomatic bone fractures. The most prevalent fractures were on right side. In our study the commonest presenting feature is subconjuctival haemorrhage (92%) followed by circum orbital ecchymosis (90%), Trismus (61%), malar flattening (60%) and numbness in the infra orbital nerve distribution (5%). In our study 52 patients with Isolated Zygomatic arch fractures were right side fractures. In our study right side fractures are more common than left side fractures. In our study Out of 52 patients with Zygomatic fractures, Isolated fracture of the Zygomatic arch was found to be most prevalent.

In our study most common clinical features are subconjuctival haemorrhage followed by circum orbital ecchymosis, Trismus and Malar flattening. Out of 52 Zygoma fractures in our study, 32 patients were treated by closed reduction (Gilles method) and 20 patients by open reduction and internal fixation.

DISCUSSION
This was an prospective, clinical study carried out on 52 patients, with Zygomatic fractures. A detailed history and examination with respect to sex, age, aetiology, nature and

In our study most common age group involved in the Zygomatic fractures was in the 2nd decade (57.69%) of life followed by 3rd decade (26.92%). In our study most common aetiology for zygomatic fractures was assaults followed by RTA and accidental falls. In our study 52 patients with Isolated Zygomatic arch fracture was most prevalent. In our study right side fractures are more common than left side fractures. In our study Out of 52 patients with Zygomatic fractures, isolated fracture of the Zygomatic arch was found to be most prevalent.

In our study most common clinical features are subconjuctival haemorrhage followed by circum orbital ecchymosis, Trismus and Malar flattening. Out of 52 Zygoma fractures in our study, 32 patients were treated by closed reduction (Gilles method) and 20 patients by open reduction and internal fixation.

Figure-3: Shows type of surgical treatment.
type of injury and clinico-symptomatology, management and complications were analysed. In our study there is clearly male predominance (96.15%) with a male to female ratio of 26:1, it is in concordance with the study of Yahya A. Ali (82.60%), Ozay ozkaya1 (75.5%), Kamulegeya A1 (88.6%), Phillipo L Chalya et al1 (72.7%), Chandra Sekhar BR (83%) and also with other studies Males are at greater risk due to their greater participation in high risk activities which increases their exposure to risk factors such as driving vehicles and social life. In our study most no of zygoma fractures occurred in the age group of 21-30years (57.69%), it is similar to the study done by Suneel kumar Punjabi et. al1 (45.15%) and Col PK Chattopadhyay et.al1a and Qadeer-ul-hassan et.al1f (47.6%). In this study patients (51.92%) were reported due to interpersonal violence, which is the most common cause in our study, it is similar to Z.Haider et al10 and much higher than Chandrasekhar BR (16.3%), Phillipo L Chalya et al11 (16.2%), Bernardo Ferreira Brasileiro et al11a (22.6%), Jefferson Viapiana Paes et al11b (14.9%). The most likely explanation to this increase in fractures due to fist fights might be a reflection of the prevalence of violence in todays society.19 In this study assaults were associated with fights under influence of alcohol, poverty. The present study shows that the second common cause of maxillofacial injuries was Road traffic accidents10,11 (42.30%) was in consistent with other study.2 The increasing number of RTA’s in developing countries like INDIA may be attributed to many factors like sharing of road ways by pedestrians and animals with fast moving and slow moving vehicles on road, low driving standards, large number of over loaded buses and autos responsible for increasing RTA’s in recent times. Driving under the influence of alcohol was contributing to high no of admissions with facial fractures which are reducing over weekends due to stricter implementation of law. In our study falls (5.78%) were the third most common risk factor. It is similar to Ozay Ozkaya et al12 (12.3%) Chandrasekhar BR (13.6%), Phillipo L Chalya et al13 (14.3%), Bernardo Ferreira Brasileiro et al13a (17.9%). In all the above studies falls was the third most common cause. In our study the majority of zygoma fractures are due to assaults (51.92%), compared to the study done by Col PK Chattopadhyay et.al (80%) by Atta-ur-Rehman et al11 (76.5%) zahur qayyum et al11 (52.5%), suneel kumar Punjabi et al11 (50%). In our study right side (51.92 %) fractures are more than left side (48.07%), this is more than that in Z. haider et al10 (42.59%) similar to study done by suneel kumar et al (Rt 55%,Lt 45%). In our study isolated Zygomatic arch fractures were higher 51.92% compared to 10.51% in Petrus Pereira Gomes et al.17 Gilles technique was used to elevate Zygomatic fracture in 61.54% of patients compared to 95.3% in PMcLoughlin et al.14 There was infraorbital nerve hypoaesthesia in 8% of patients with Zygomatic complex fractures compared to 10% in Rafael et al.15 There was complete recovery in these patients by 6 weeks. Closed reductions of zygoma fractures were done in 61.54% of patients Knight and North type II, and ORIF was done in Knight and North Group IV and V in 48.08% in our study. The threshold for fixation of displaced Zygomatic complex was slightly higher (80%) compared to P.McLoughlin et al 75%.14 There were two patients with Diplopia which improved after release of entrapped muscle by open reduction compared to Tymour Fourazanfar etal where Orbital floor reconstruction was needed.36 Single point fixation was done in 17 patients at ZygomaticoMaxillary buttress and 3 patients had 2 point fixation at Zygomatico-Maxillary and Zygomatico-Frontal sutures.15-18 Satisfactory alignment was noted in moderately displaced fractures Knight and North Group IV fractures with even single point fixation. Over all complication rate (wound infection) in 20 patients treated by Open reduction and internal fixation was 5% compared to 8.6% in study by Robert Chuong et al.16 Among studied patients with Isolated Zygoma fracture 2 patients had infraorbital nerve paraesthesias which settled by 6 weeks. One patient with Group II Knight and North classification had mild Malar flattening post op but patient was not keen to pursue surgery. Post operatively patients were followed up in our patient clinic for upto 12 weeks.

CONCLUSION

The high frequency of Zygomatic fractures due to RTA in our population highlights the need for the strict enforcement of traffic rules and regulations. Also there is the need for repair of bad roads and the resuscitation of the rail transport system as an alternative to road transport for man and goods. In view of the avoidable morbidity and mortality due to inadequate treatment, we advocate the establishment of regionalized, efficient, and focused trauma centers in various parts of the state particularly for acute trauma.
